Figure ECGs and head CT/CTA

Preoperative ECG shows diffuse T-wave inversions (QTc 459 msec) (A). Noncontrast head CT shows a right peri-insular hyperdensity (B, arrow); CTA shows one right middle cerebral artery aneurysm compressing the insula (arrow) and two other aneurysms (arrowheads) (C). Postoperative ECG shows reversal of T-waves in precordial leads (QTc 408 msec) (D).

From the Department of Neurology (S.M., J.R.S.), Division of Neurocritical Care and Stroke, and Department of Radiology (J.R.S.), Massachusetts General Hospital, Harvard Medical School, Boston; and Department of Neurology (R.P.G.), University of Massachusetts Medical School, Worcester.

Disclosure: The authors report no conflicts of interest.

A 41-year-old woman developed temporary substernal chest pain. Physical examination was normal. ECG showed diffuse T-wave inversions with nonfamilial/non-medication-related QTc prolongation (figure, A) persisting despite the resolution of chest pain after sublingual nitroglycerin. Normal serum/urine toxicology, cardiac enzymes, transthoracic echocardiogram, and resting Technetium-99m sestamibi study raised the suspicion for cerebral T-waves. Head CT/CT-angiogram (CTA) revealed a middle cerebral artery aneurysm compressing the cardunculus,¹ in the right anterior inferior insula

(figure, B and C). Partial ECG normalization (figure, D) by cardunculus decompression (1 month after aneurysm clipping) supports that it is the regulator of sympathetic cardiac outflow balance.^{1,2}
