Figure 1 Sagittal CT

Imaging shows evidence of dural ectasia with posterior vertebral body scalloping (arrowhead). A mild L4/5 anterolisthesis is present.

A 20-year-old man with neurofibromatosis I presented with back pain and altered sensation in the lower limbs without a radicular distribution and normal power. He subsequently developed urinary retention and reduced sensation to the level of T10. MRI and CT examinations performed to exclude cord compression demonstrated dural ectasia (expansion of the dural sac) resulting in elongated lumbar pedicles and bilateral chronic fractures (figures 1 and 2). Pedicular fractures are a recognized but rare

Figure 2 Axial CT

The lumbar pedicles were elongated and thinned with bilateral pedicular fractures (arrows). The fractures showed no edema on MRI suggesting chronic nonunited fractures.

complication of dural ectasia.¹ It is postulated that pedicular weakness secondary to thinning relate to dural ectasia and result in stress fractures.²
