Figure 1 Polymyalgia rheumatica

Sagittal (A) and axial (B) postcontrast T1-weighted MRI show ill-defined enhancement in the posterior paraspinal soft tissues centered at the supraspinous bursae of the lower cervical spine (arrows).

A 62-year-old woman presented with 4 months of neck, shoulder, and hip pain, morning stiffness, and elevated inflammatory markers compatible with polymyalgia rheumatica (PMR). Cervical spine imaging demonstrated ill-defined enhancement in posterior neck soft tissues (figure 1), consistent with interspinous bursitis.¹ She reported right-sided headache. Brain magnetic resonance angiography

Figure 2 Giant cell arteritis

3D maximal intensity projection magnetic resonance angiography image shows severe narrowing of the anterior branch of the right superficial temporal artery (arrow).

Figure 3 Follow-up

Subsequent color Doppler ultrasonography of the left superficial temporal artery obtained while on prednisone therapy shows a hypoechoic halo around the lumen of the artery (arrows), representing wall edema (A). Color Doppler ultrasonography of the normal ipsilateral facial artery is shown for comparison (B).

demonstrated narrowing of the anterior branch of the right superficial temporal artery (STA; figure 2). Right STA biopsy showed giant cell arteritis. Giant cell arteritis occurs in 16% to 21% of patients with PMR.² Color Doppler ultrasound of the left STA obtained while on prednisone showed a hypoechoic halo (figure 3).³

AUTHOR CONTRIBUTIONS

Daniel Ginat: drafting/revising the manuscript, analysis or interpretation of data, accepts responsibility for conduct of research and final approval. Naina Rastalsky: drafting/revising the manuscript, analysis or interpretation of data, accepts responsibility for conduct of research and final approval, acquisition of data.

STUDY FUNDING

No targeted funding reported.

DISCLOSURE

The authors report no disclosures relevant to the manuscript. Go to Neurology.org for full disclosures.
