Supplemental data at
www.neurology.org

A 30-year-old man with a history of generalized epilepsy presented with progressively worsening involuntary movements for 2 years. He had no family history of movement disorders. He had orofacial choreiform movements with sucking, grimacing, and neck flexion, which were exacerbated with eating. He also had oral ulcers due to involuntary biting. Blood smear showed 20% acanthocytes. Nerve conduction demonstrated sensory axonal neuropathy. MRI was negative for white matter changes and caudate atrophy. Orofacial dyskinesia (video on the *Neurology*[®] Web site at www.neurology.org), oral mutilation, and feeding dystonia are typical of chorea-acanthocytosis.¹ Generalized seizures and axonal sensory neuropathy are associated.²

AUTHOR CONTRIBUTIONS

All authors were involved in the diagnosis and management of the patient. Dr. Gooneratne and Dr. Weeratunga were involved in preparing the video and manuscript.

STUDY FUNDING

No targeted funding reported.

DISCLOSURE

The authors report no disclosures relevant to the manuscript. Go to Neurology.org for full disclosures.
