A 38-year-old woman presented with an 8-year history of progressive dysarthria, gait disturbance, and hyperreflexia. MRI revealed leukodystrophy involving brainstem with pial signal changes and spinal cord atrophy (figure 1). Brain biopsy showed Rosenthal fibers (figure 2). She had a de novo mutation of the glial fibrillary acidic protein (GFAP) gene (c.799G>C causing p.Ala267Pro).

Alexander disease is caused by gain-of-function mutation of the GFAP gene. GFAP is an intermediate filament, and mutations result in astrocytic accumulation of eosinophilic inclusions known as Rosenthal fibers.1 Late-onset patients show brainstem features (ataxia, dysphagia, dysphonia, and palatal myoclonus) with hindbrain-predominant leukodystrophy and spinal cord atrophy.1,2

**AUTHOR CONTRIBUTIONS**

Drs. Keon-Joo Lee and Jangsup Moon: drafting the manuscript. Drs. Keon-Joo Lee, Jangsup Moon, and Soon-Tae Lee: study concept, design, and chart review. Dr. Soon-Tae Lee: critical revision of the manuscript and funding support.

**STUDY FUNDING**

Supported by a grant (A121911) of the Korean Health Technology R&D Project, Ministry of Health & Welfare, Republic of Korea.

**DISCLOSURE**

The authors report no disclosures relevant to the manuscript. Go to Neurology.org for full disclosures.

**REFERENCES**

Hematoxylin & eosin staining of the white matter biopsy showed typical morphology of Rosenthal fibers (arrowheads). Rosenthal fibers are beaded, elongated, or corkscrew-shaped intracytoplasmic inclusions that represent accumulation of intermediate filament. Rosenthal fibers are seen in neoplasms (such as pilocytic astrocytomas), Alexander disease, and reactive tissues with gliosis.
