Cerebral air embolism

Timea Hodics, MD, and Italo Linfante, MD, Boston, MA

A 35-year-old man developed tension pneumothorax 2 days after a right upper lobectomy with resection of an aspergiloma. During CT-guided chest tube placement, he suddenly developed decreased responsiveness, conjugate eye deviation to the right, left face, arm, and leg weakness with sensory deficit (NIH Stroke Scale [NIHSS] = 25). Head CT showed air in the right cortical middle cerebral artery (MCA) branches (figure, A). Diffusion-weighted imaging showed increased signal intensity in the cortical right MCA territory (see figure, B). Induced hypertension and hyperoxygen treatment led to gradual improvement until full recovery in 1 week (NIHSS = 0). There was no evidence of infarction on follow-up MRI examination.
