A 47-year-old woman reported burning abdominal discomfort, urinary retention, and leg paresthesias 1 week after dental cleaning. Examination revealed right leg weakness and sensory loss to T10. MRI showed an intramedullary ring-enhancing lesion at T8 (figure, A). By day 7, she was paraplegic with a T3 sensory level. Repeat MRI showed edema from C3 to the conus medullaris, with C7 to T11 enhancement (figure, B). Urgent abscess drainage was performed. Paraplegia and a T4 sensory level remained despite radiographic resolution (figure, C). Cultures revealed oral flora. Early broad-spectrum antibiotic therapy is indicated when intramedullary spinal cord abscess is suspected.

This information is current as of April 9, 2007
group of cases who were asymptomatic and ≥75 years old. The major factor driving inappropriateness among asymptomatic patients was the degree of comorbid illness burden. Asymptomatic patients ≥75 years old had the same distribution of comorbidity compared with those <75 years old (p = 0.98). While age itself was not a factor in the appropriateness ratings, we found no differences in rates of inappropriate CEA comparing asymptomatic patients who were ≥75 years old to all other patients (8.2% vs 8.8%, p = 0.34).

Reclassifying all asymptomatic patients ≥75 years old as having uncertain appropriateness, as Dr. Chaturvedi discusses, would substantially raise the proportion considered uncertain (by shifting many patients out of the appropriate category). The proportion considered inappropriate would not change. Thus, our main finding, that since publication of the RCTs rates of CEA for inappropriate reasons fell from 32% to 8.6%, would not be affected.1

CORRECTION
Paraplegia caused by invasive spinal aspergillosis
In the NeuroImage “Paraplegia caused by invasive spinal aspergillosis” by P.C. Karakousis (Neurology 2007;68:158), the fifth sentence should read as follows: “MRI studies revealed an edematous spinal cord from C5 through the conus with multiple high-signal T2 lesions (figure, A); postgadolinium T1 images (not shown) demonstrated multiple enhancing intramedullary masses.”
The figure legend should read as follows:
Figure. (A) T2 weighted sagittal MRI of the spine 8 months after the onset of paraparesis, indicating multiple intradural, intramedullary masses (arrows); postgadolinium T1 images (not shown) demonstrated multiple enhancing intramedullary masses. Gomori methenamine silver stain.
The authors regret the error.

CORRECTION
Intramedullary spinal cord abscess in a healthy woman
In the NeuroImage “Intramedullary spinal cord abscess in a healthy woman” by A. Applebee et al. (Neurology 2007;68:1230), there is an error describing the images. All three of the images are fat-suppressed T1 postcontrast images. The figure legend should read as follows:
Figure. (A) Sagittal fat-suppressed T1 postcontrast MRI of the thoracic cord (day 1) demonstrates an intramedullary ring enhancing lesion at T8. (B) Sagittal T1 postcontrast (day 4) showing enlargement of the lesion extending superiorly to T3 and inferiorly to T11. (C) Sagittal T1 postcontrast image (1 year out) with resolving abnormal signal at T6-T9.
The authors regret the error.
