A 64-year-old man was referred to us for suspected normal pressure hydrocephalus (NPH), according to the clinical history of gait disturbance and urge incontinence, and radiologic evidence of a supratentorial hydrocephalus, with enlarged pericerebral spaces (figure 1). A new MRI revealed a 4-cm prepontine arachnoid cyst (figure 2). An endoscopic ventriculo-cystostomy was performed with a prompt improvement of symptoms.

Eighty-five percent of prepontine arachnoid cysts occur in children; most of them present with acute/subacute signs of increased intracranial pressure. The possibility of diagnosing these lesions in adults has been reported; only two cases have been described in the elderly, none of whom had symptoms of NPH.1,2
