Teaching NeuroImages: Brucellosis mimicking demyelinating disease

A 57-year-old man presented with a 4-week history of fever, visual loss, and progressive ataxic gait. He worked as a truck driver and had been in contact with raw sheepskin a few months prior. Neurologic examination showed drowsiness, pseudobulbar syndrome, hyperreflexia, ataxia, and optic disc edema. He had a lymphocytic pleocytosis and diffuse hyperintense white matter lesions on brain MRI (figure). Serum and urine PCR were positive for *Brucella* spp. Rheumatologic and other serologic tests were negative. Partial improvement was achieved with doxycycline, rifampin, and trimethoprim-sulfamethoxazole.

Brain MRI suggesting demyelinating disease with atypical clinical presentation should raise other diagnostic possibilities such as nervous system infections and acute disseminated encephalomyelitis.1,2
