A 56-year-old man with no past medical history developed a left facial droop, dysarthria, and left arm weakness. He was found to have an acute right thalamic hemorrhage. On further examination, he was found to have right-sided ptosis and miosis, with anisocoria more marked in the dark than in light (figure, A). He was also found to have right-sided facial anhidrosis.

CT angiogram showed no evidence of carotid dissection. The patient’s Horner syndrome was due to a first-order neuron lesion in the posterior nucleus of the right hypothalamus or proximal CNS sympathetic tract (figure, B and C).1,2
