SUBTHALAMIC DEEP BRAIN STIMULATION
AT INDIVIDUALIZED FREQUENCIES FOR
PARKINSON DISEASE

Erwin B. Montgomery, Jr., Birmingham, AL:

Tsang et al. noted frequencies of gamma oscillations recorded from the subthalamic nucleus (STN) and the clinically optimal deep brain stimulation (DBS) frequencies, expecting them to be the same or harmonics. This would be reasonable assuming a single harmonic oscillator for each frequency band and resonance between the oscillator and DBS. This is consistent for nonlinear oscillators in loosely coupled networks as shown in mathematical models. Such oscillators, including DBS, can interact when frequencies are commensurate (their ratio is a rational number) and not just harmonic. Such an oscillator can be driven at its fundamental frequency by another of a different frequency.

The basal ganglia-thalamic-cortical system can be considered a loosely coupled system of polysynaptic reentrant oscillators whose components are nonlinear. Recordings in nonhuman primates demonstrated that individual neurons entrain multiple frequencies simultaneously and demonstrated multiple resonance frequencies to a single DBS frequency. Furthermore, local field potentials represent summed activity in the dendritic trees across many neurons. The risk is attribution of the resultant oscillation to the single volume, thus single oscillator, when in fact the oscillations within the volume are many and different, including phase as well as frequency.

RISK OF FRACTURES IN PATIENTS WITH MULTIPLE SCLEROSIS: A POPULATION-BASED COHORT STUDY

Ruth Dobson, Sreram Ramagopalan, Gavin Giovannoni, London:

Bazelier et al. address the important issue of fracture risk in multiple sclerosis (MS) yet the discussion does not go far enough. Use of anxiolytics/hypnotics and antidepressants was strongly associated with fracture risk. These treatments have also been associated with an increased risk of both falls and fractures in large population-based studies. Given the increased risk of falling associated with MS, the recommendation to avoid anxiolytics/hypnotics wherever possible and to increase awareness of the falls risk associated with antidepressants in MS is important.

The authors discuss short-course IV glucocorticoids, used during relapses, as a contributor to fracture risk. Although one study associated glucocorticoid use with fracture risk, this has not been replicated. The potential for rapid improvement in mobility following glucocorticoid treatment during relapse may have beneficial effects.

A more proactive approach is required in MS. We propose all patients with MS should have formal...
fracture risk assessment (FRAX) and falls assessment annually, with a baseline bone mineral density scan to identify those at high risk of osteoporotic fracture. Potential contributors to fracture risk should be avoided where possible, and interventions to improve both bone health and falls risk should be routine.

Author Response: Marloes T. Bazelier, Frank de Vries, Utrecht, the Netherlands: We appreciate the comments by Dobson et al. and agree with their concerns about the use of anxiolytics/hypnotics and antidepressants in patients with MS. These medication types have been associated with falls and (hip) fractures. However, there is no evidence that discontinuation of these drugs would prevent fractures. We also agree that epidemiologic evidence for the underlying etiology of glucocorticoid use and risk of fractures in patients with MS is unclear. Because patients with MS are already at risk of fracture, FRAX scores may be underestimated. Unfortunately, FRAX has not been designed specifically for patients with MS. We have recently published a clinical risk score that has been developed for fracture risk assessment in patients with MS.

Plasma multianalyte profiling in mild cognitive impairment and Alzheimer disease
In the article “Plasma multianalyte profiling in mild cognitive impairment and Alzheimer disease” by W.T. Hu et al. (Neurology® 2012;79:897–905), there is an error in the first paragraph on page 899. The third sentence should read “At WU, blood was collected in EDTA in polypropylene tubes after overnight fasting between 7:30 and 8:00 AM and centrifuged (2,000 g × 15 minutes at 4°C) for separation into plasma and cellular components.” The authors regret the error.

WriteClick: Editor’s Choice: Predicting outcome after acute basilar artery occlusion based on admission characteristics
In the correspondence regarding the article “Predicting outcome after acute basilar artery occlusion based on admission characteristics” by Y. He et al. (Neurology® 2012;79:1410), there is an error in the second author’s name, which should be spelled “Tianxiao Li.” The editorial staff regrets the error.
