Carotid dissection following a generalized tonic-clonic seizure

A 37-year-old woman experienced a generalized tonic-clonic seizure. Subsequent to the seizure, the patient observed left-sided face and neck pain. A left Horner syndrome was noted on examination. An MRI and magnetic resonance angiogram revealed a left skull base carotid artery dissection without infarction (figure, A and B). Previous MRI had shown normal carotid flow voids. The patient was treated conservatively and magnetic resonance angiogram 1 month later revealed recanalization (figure, C).

Carotid artery dissection has an incidence of 1.72 per 100,000.¹ Although carotid artery dissection is reported in association with minor trauma, there are no reports occurring in association with a seizure.²
