

## In Focus

### Spotlight on the October 22 Issue

**Robert A. Gross, MD, PhD, FAAN**  
Editor-in-Chief, *Neurology*<sup>®</sup>

#### **Omega-3 fatty acids and domain-specific cognitive aging: Secondary analyses of data from WHISCA**

The authors assessed the relationship between prerandomization red blood cell docosahexaenoic acid + eicosapentaenoic acid levels and cognitive function in 2,157 cognitively normal women. After adjustment for demographic, clinical, and behavioral characteristics, there were no cognitive differences at the time of the first annual cognitive battery or in the rate of cognitive change.

See p. 1484

#### **A lipid storage-like disorder contributes to cognitive decline in HIV-infected subjects**

A quantitative lipidomic analysis was conducted on 524 longitudinal CSF samples. Subjects included HIV-infected individuals with longitudinal clinical and cognitive test data and cognitively normal HIV-negative healthy controls. HIV infection and combination antiretroviral therapy (cART) were independently associated with a CNS metabolic disturbance, identifying surrogate markers prognostic for cognitive decline.

See p. 1492

From editorialists Gelbard & Gendelman: "We must continue to focus on what happens to the entire CNS and peripheral ecosystem as people treated with cART continue to live and age with HIV-1."

See p. 1480

#### **Encephalitis and GABA<sub>B</sub> receptor antibodies: Novel findings in a new case series of 20 patients**

This study showed that GABA<sub>B</sub> receptor (GABA<sub>B</sub>R) antibodies are predominantly associated with limbic encephalitis but also occur in some patients with ataxia or opsoclonus. Detection of GABA<sub>B</sub>R antibodies is

important because more than half of these patients have a small-cell lung cancer with neurologic symptoms that respond well to therapy, regardless of the association with a neoplasm.

See p. 1500; Editorial, p. 1482

#### **Copy number variants are frequent in genetic generalized epilepsy with intellectual disability**

Copy number variants (CNVs) are recognized genetic determinants of epilepsy. In patients with genetic generalized epilepsy with intellectual disability, there was a considerably higher rate of recurrent genetic generalized epilepsy microdeletions (10%) and of all CNVs (28%) than in those of normal intellect. CNV testing is important in these patients.

See p. 1507

#### **Prognostic or predictive value of MGMT promoter methylation in gliomas depends on IDH1 mutation**

Patients of the NOA-04 trial with known MGMT and IDH1 status were analyzed for interdependency of the prognostic vs predictive role of MGMT promoter methylation from IDH1 or 1p/19q status and treatment. MGMT promoter methylation was a predictive biomarker for benefit from alkylating agent chemotherapy in patients with IDH1-wild-type, but not IDH1-mutant, malignant gliomas.

See p. 1515

#### **Unrecognized vitamin D<sub>3</sub> deficiency is common in Parkinson disease: Harvard Biomarker Study**

The authors used liquid chromatography/tandem mass spectrometry to establish a specific association between deficiency of 25-hydroxy-vitamin D<sub>3</sub> and Parkinson disease in 388 patients and 283 controls free of neurologic disease. This study suggests that many patients with Parkinson disease may be vitamin D-deficient, and that this deficiency is relevant for optimal care.

See p. 1531

#### **SPECIAL ARTICLE**

#### **Quality improvement in neurology: Dementia management quality measures**

These measures recognize the challenge dementia presents to patients and their caregivers, health care providers, public health officials, and government and private insurers. While we await more effective disease-modifying treatments for patients with dementia, the measures outlined here will improve the quality of life for patients with dementia and their caregivers.
