Mystery Case: Giant mature teratoma of the lateral ventricle in a child

A 3-year-old girl was admitted with a 1-month history of headache. Neurologic examination was normal. Cranial CT revealed a mass with huge calcification in the right lateral ventricle (figure 1A). MRI demonstrated a lesion with low and high signal intensity and heterogeneous enhancement (figure 1, B–D). A right frontal craniotomy was performed. The right ventricle was found to be filled with sebaceous glands, hair, fat globules, a full set of teeth, tongue, and gastrointestinal glands (figure 2, A–D). Histologic examination confirmed a mature teratoma. Postoperative MRI demonstrated total tumor resection (figure 2, E and F). A mature teratoma located in the lateral ventricle with a full set of teeth is extremely rare.1,2

AUTHOR CONTRIBUTIONS
Dr. Li: data collection, drafting of manuscript. Dr. Lan: data collection, review of literature. Dr. Xu: revision of manuscript, concept of manuscript.

STUDY FUNDING
No targeted funding reported.

DISCLOSURE
The authors report no disclosures relevant to the manuscript. Go to Neurology.org for full disclosures.

REFERENCES
The resected samples show the sebaceous glands and hair (A), a full set of teeth (B), tongue (C), and gastrointestinal glands (D). Postoperative MRI, contrast axial (E) and sagittal (F) images, shows total tumor resection.

MYSTERY CASE RESPONSES

The Mystery Case series was initiated by the Neurology® Resident & Fellow Section to develop the clinical reasoning skills of trainees. Residency programs, medical student preceptors, and individuals were invited to use this Mystery Case as an educational tool. Responses were solicited through a group e-mail sent to the American Academy of Neurology Consortium of Neurology Residents and Fellows and through social media.

All the responses we received came from individuals rather than groups. A total of 33% of respondents correctly identified the lesion as a teratoma. The most complete response came from Violet M. Aroon, who pointed out that the heterogeneous lesion likely contains fat and soft tissue based on its signal characteristics on T1 and T2 MRI.

This case highlights the value of MRI in characterizing intraventricular mass lesions, which may be essential in guiding subsequent clinical management.
