Infratentorial dural arteriovenous fistula resulting in brainstem edema and enhancement

A 65-year-old man presented with a 2-year history of progressive eye movement abnormalities, bilateral limb weakness, and gait instability. MRI (figure 1) showed T2 hyperintensities in brainstem and cerebellum with enhancement, which were initially diagnosed as tumor. Closer inspection revealed prominent vascular structures at the tentorium. Digital subtraction angiography (DSA) showed an infratentorial dural arteriovenous fistula (DAVF) (figure 2). Following embolization with glue, the bilateral limb weakness improved and the other symptoms had resolved at discharge the next day.

Although DAVFs rarely have infratentorial localization, if MRI raises suspicion for it, DSA is the gold standard for diagnosis.\(^1,2\)

Author contributions: Bart J. Emmer: acquisition of data and case description. Adriaan C.G.M. van Es: acquisition of data and critical review of manuscript. Peter J. Koudstaal: acquisition of data and critical review of manuscript. Stefan D. Roosendaal: acquisition of data and critical review of manuscript.

Figure 1  MRI at presentation

(A) T2-weighted image with hyperintensities in the brainstem and cerebellum (open arrows). (B) Sagittal fluid-attenuated inversion recovery shows swelling of cerebellar tonsil and hyperintensity (asterisk). (C) After gadolinium contrast, there is inhomogeneous enhancement of the hyperintense T2 areas (arrowhead). (D) Infratentorial extra-axial prominent vessels (arrow) are seen.
Study funding: No targeted funding reported.
