A 4-year-old girl was referred for a painless heterochromia iridis and a loss of visual acuity. Funduscopic examination revealed a total retinal detachment (RD) associated with a vitreous hemorrhage.

Ultrasonography and an ocular MRI showed a total RD with a calcification on the temporal retinal fold (figure 1), suggestive of a diffuse infiltrating retinoblastoma.

Histology shows a diffuse infiltrating retinoblastoma.

An enucleation was performed and pathologic examination confirmed the diagnosis of a differentiated diffuse infiltrating retinoblastoma (figure 2). This entity is rare but must be suspected in case of a calcified retinal detachment in a young child.1,2

Author contributions
A. Lecler and C. Friang: study concept and design; acquisition, analysis, and interpretation of data. P. Freneaux and G. Caputo: acquisition of data.

Study funding
No targeted funding reported.
