Figure 1 Neologism during ideographic handwriting

(A) Incomprehensible characters indicated by the patient to reflect “multidimensional meanings of the world.” (B) Accurate word copying with additional ideographic recreation of the word “peremptory” (red arrows).

A 48-year-old man had received embolotherapy for bronchiectasis-induced severe hemoptysis 1 week before and presented with acute drowsiness of 10 hours. Neuropsychiatric assessment revealed hypersomnolence, amnesia, confabulation, visual hallucination, grandiose delusion, anomic aphasia, and neologism during ideographic handwriting (figure 1). MRI showed acute ischemic stroke involving the thalamic region supplied by left paramedian artery^{1,2} (figure 2). Aspirin and atorvastatin were initiated. His symptoms persisted for 15 days but improved significantly with 2 mg risperidone after 1 week, and he almost fully recovered 1 month later. Visual hallucination, delusion, and ideographic neologism are atypical symptoms of single left paramedian infarct.^{1,2}

Study funding

No targeted funding reported.
