Study question

Does the association between risk factors and incident ischemic and hemorrhagic stroke differ by sex?

What is known and what this paper adds

There are considerable differences between women and men in the clinical presentation, medical care, and prognosis and outcomes of stroke. This investigation's results provide further evidence that several risk factors are more strongly associated with the risk of any stroke or stroke subtypes in women compared with men.

Methods

For this cohort study, the investigators analyzed data from the UK Biobank study, which recruited 40–69-year-old UK residents through 22 centers between 2006 and 2010. These analyses focused on 263,295 women and 208,676 men who had no history of cardiovascular disease at baseline. The UK Biobank participants underwent baseline clinical assessments that included measurements of various stroke risk factors, and national hospital admissions data and the national death register were used to identify cases of incident stroke occurring by February 1, 2018. Cox regression models were used to estimate hazard ratios (HRs) for various stroke risk factors, by sex. The primary outcomes were female-to-male HR ratios (RHRs) for selected risk factors.

Results and study limitations

Over follow-up (median duration, 9 years), 4,662 cases of stroke occurred. The incidence of stroke per 10,000 person-years was 8.66 (95% CI, 8.29–9.04) for women and 13.96

Table Selected RHRs for stroke subtypes (BP = blood pressure)

Risk factor comparison	RHR (95% CI) for:	
	Ischemic stroke	Hemorrhagic stroke
Stage 2 hypertension v normal BP	1.32 (1.20–1.44)	1.27 (1.05–1.53)
Current smoking v not smoking	1.05 (0.89–1.24)	1.31 (0.87–1.97)
Low SES v high	1.22 (1.06–1.41)	0.97 (0.69–1.35)

(95% CI, 13.44–14.50) for men. Several stroke risk factors were stronger in women than in men, including stage 2 hypertension (RHR, 1.36; 95% CI, 1.26–1.47), current smoking (RHR, 1.18; 95% CI, 1.02–1.36), and low socioeconomic status (SES; RHR, 1.17; 95% CI, 1.03–1.33). However, the analyses revealed no such sex difference for diabetes, atrial fibrillation, or 1-SD changes in blood pressure, body anthropometry indices, or blood lipid levels. The present study's limitations include self-reported data, small event counts for stroke subtypes, and a reliance on a relatively healthy and predominantly white cohort, which may limit generalizability.

Study funding and competing interests

This study was funded by the UK Medical Research Council and the National Health and Medical Research Council of Australia. Some authors report additional competing interests. Go to Neurology.org/N for full disclosures.

A draft of the short-form article was written by M. Dalefield, a writer with Editage, a division of Cactus Communications. The corresponding author(s) of the full-length article and the journal editors edited and approved the final version.
