Figure 1 MRI Axial Images Showing Diffusion Restriction and Corresponding ADC Reversal Suggestive of Acute Infarct in Left Inferior Parietal Lobe (A–B); FLAIR Showing Gliotic Scar in Left Parietal Lobe (C); Angiogram Showing Left M2 Stenosis (D)

A 56-year-old hypertensive man presented with left-sided weakness of 2-hour duration. He made complete recovery from right hemiparesis because of left parietal infarct. Examination showed dysarthria and left hemiparesis (NIHSS 8/42). MRI brain showed both left parietal acute infarct and gliosis from old infarct (Figure 1). He was successfully thrombolysed with intravenous alteplase. Present stroke was diagnosed as ipsilateral hemiparesis, confirmed by diffusion tensor imaging (Figure 2). Ipsilateral hemiparesis, mostly seen with posterior fossa malformations and remote infarctions,¹ results from injury to uncrossed corticospinal tract (CST) in patients of remote brain injury or with no decussation of CST or injury to ipsilateral extrapyramidal motor pathway.²
