A 74-year-old man presented with right watershed infarction (initial gadolinium-injected MRI, Figure). Renal function was normal. MRI 4 hours later showed ipsilateral perivascular spaces (PVS) and subarachnoid fluid-attenuated inversion recovery (FLAIR) hyperintensities, and complete resolution of subarachnoid/perivascular FLAIR abnormalities was observed 10 days later.

From the Department of Neurology, Nîmes University Hospital, France.

probably related to stroke-associated delayed gadolinium leakage (Figure). MRI after 10 days showed complete resolution of subarachnoid/perivascular abnormalities (Figure).

Stroke-related subarachnoid and ocular gadolinium leakage on FLAIR probably represents blood–brain/ocular barrier disruption. \textsuperscript{1,2,e1} An earlier report described PVS gadolinium leakage on MRI performed >1 month after stroke.\textsuperscript{e1} The glymphatic system (playing a role in CSF–interstitial fluid interchange) may be involved in stroke-related blood–brain barrier leakage observed in the subarachnoid space and PVS.

**Study Funding**
The authors report no targeted funding.

**Disclosure**
The authors do not have any financial or other contributions to disclose. Go to Neurology.org/N for full disclosures.
