Figure 1 Brain MRI Findings of an NIID Patient During Encephalopathy-like Episode

(A, arrow) Diffusion-weighted images showing high signals along the corticomedullary junction; the corresponding ADC images also show similar findings (B, arrow). (C, arrow) Postcontrast MRI showing enhanced lesions distributed in the left occipital lobe cortex and no enhancement in the right occipital lobe cortex. (D, arrow) Postcontrast MRI showing enhanced lesions distributed in the right occipital lobe cortex and no enhancement in the left occipital lobe cortex.

A 66-year-old woman developed behavioral abnormalities and altered sensorium and showed high signals along the corticomedullary junction on diffusion-weighted image (Figure 1A) and the corresponding ADC images (Figure 1B). Postcontrast magnetic resonance imaging showed enhancement of the left occipital lobe cortex (Figure 1C). One year later, she had recurrence of the same
symptoms and her MRI showed enhancement of the right occipital lobe cortex (Figure 1D). These imaging findings correlated with her reversible encephalopathy episodes, manifested by behavioral abnormalities and altered sensorium. Finally, a diagnosis of neuronal intranuclear inclusion disease (NIID) was established based on skin biopsy (Figure 2A, B) and genetic testing.

Occipital cortical enhancement may be a diagnostic clue for NIID in patients with reversible encephalopathy episodes.  

**Study Funding**

This study was supported by the Project of Hunan Health Committee (No. 202103070437).

**Disclosure**

The authors report no disclosures relevant to the manuscript. Go to Neurology.org/N for full disclosures.

**Publication History**

Received by Neurology January 28, 2022. Accepted in final form August 12, 2022. Submitted and externally peer reviewed. The handling editor was Roy Strowd III, MD, Med, MS.
