In Focus

José G. Merino, MD, MPhil, Editor-in-Chief, Neurology®

Notable in Neurology This Week
This issue features an article that examines lexical and acoustic speech features relating to Alzheimer disease pathology; another analyzes the effect of positive airway pressure therapy on the incidence of cognitive disorders and decline in adults with obstructive sleep apnea. A featured review highlights blood pressure variability after cerebrovascular events as a possible new therapeutic target.

Articles

Association of Plasma Biomarker Levels With Their CSF Concentration and the Number and Severity of Concussions in Professional Athletes
This study examined whether biomarkers of axonal injury, astroglial injury, and amyloid pathology in plasma were associated with CSF concentrations and duration of postconcussion syndrome due to repetitive head impacts (RHIs) in professional athletes. Biomarkers measured in plasma were not associated with CSF measures, suggesting that CSF measures are more useful in the diagnosis of late effects of RHIs.

Impact of Seizure Recurrence on 1-Year Functional Outcome and Mortality in Patients With Poststroke Epilepsy
This prospective observational cohort study investigated the functional outcome and mortality of patients with poststroke epilepsy (PSE), analyzing the effect of seizure recurrence on said outcomes. Seizure recurrence was associated with functional decline but not with mortality, suggesting that early and adequate antiseizure treatment may prevent functional deterioration in patients with PSE.

In-Hospital Outcomes and Recurrence of Acute Ischemic Stroke in Patients With Solid Organ Malignancy
Outcomes of ischemic stroke among patients with solid organ malignancy vary according to the malignancy type and use of acute stroke interventions. This study found that patients with lung cancer have worse in-hospital outcomes despite the use of acute reperfusion therapies and patients with lung and pancreatic cancers experience a higher risk of recurrent stroke.

Observational Study of Neuroimaging Biomarkers of Severe Upper Limb Impairment After Stroke

This study investigated whether imaging biomarkers beyond the corticospinal tract (CST) relate to poststroke severe upper limb impairment by evaluating white matter microstructure in the corpus callosum (CC). The study identified specific white matter tracts that helped to explain motor deficits—CST with milder impairment and CC with severe impairment—and highlight that neuroimaging biomarker selection differs across subgroups.
