Diagnosis and management of dementia with Lewy bodies

Fourth consensus report of the DLB Consortium

ABSTRACT

The Dementia with Lewy Bodies (DLB) Consortium has refined its recommendations about the clinical and pathologic diagnosis of DLB, updating the previous report, which has been in widespread use for the last decade. The revised DLB consensus criteria now distinguish clearly between clinical features and diagnostic biomarkers, and give guidance about optimal methods to establish and interpret these. Substantial new information has been incorporated about previously reported aspects of DLB, with increased diagnostic weighting given to REM sleep behavior disorder and ¹²³Iodo-metadobenzylguanidine (MIBG) myocardial scintigraphy. The diagnostic role of other neuroimaging, electrophysiologic, and laboratory investigations is also described. Minor modifications to pathologic methods and criteria are recommended to take account of Alzheimer disease neuropathologic change, to add previously omitted Lewy-body-related pathology categories, and to include assessments for substantia nigra neuronal loss. Recommendations about clinical management are largely based upon expert opinion since randomized controlled trials in DLB are few. Substantial progress has been made since the previous report in the detection and recognition of DLB as a common and important clinical disorder. During that period it has been incorporated into DSM-5, as major neurocognitive disorder with Lewy bodies. There remains a pressing need to understand the underlying neurobiology and pathophysiology of DLB, to develop and deliver clinical trials with both symptomatic and disease-modifying agents, and to help patients and carers worldwide to inform themselves about the disease, its prognosis, best available treatments, ongoing research, and how to get adequate support. Neurology® 2017;89:1–13

GLOSSARY

AD = Alzheimer disease; CHEI = cholinesterase inhibitor; DAT = dopamine transporter; DLB = dementia with Lewy bodies; DSM-5 = Diagnostic and Statistical Manual of Mental Disorders, 5th edition; LB = Lewy body; MCI = mild cognitive impairment; MIBG = metaiodobenzylguanidine; MMSE = Mini-Mental State Examination; MTL = medial temporal lobe; PD = Parkinson disease; PSG = polysomnography; RBD = REM sleep behavior disorder.

The Dementia with Lewy Bodies (DLB) Consortium last reported on diagnosis and management in December 2005, and its recommendations have been widely cited for both clinical and research use.¹,² Changes made to the diagnostic criteria at that time increased diagnostic sensitivity for DLB, but detection rates in clinical practice remain suboptimal,³ with many cases missed or misdiagnosed, usually as Alzheimer disease (AD). The revised DLB criteria presented here incorporate new developments since then and result from a review process that combined the reports of 4 multidisciplinary, expert working groups with a meeting that included patient and care partner participation (appendix e-1 at Neurology.org). The Consortium recognizes increasing interest in detecting early-stage disease; prodromal DLB criteria are in development and will be reported separately.

SUMMARY OF CHANGES While maintaining their previous structure, the revised DLB clinical diagnostic criteria improve on earlier versions¹,² by distinguishing clearly between clinical features and diagnostic

bimearkers, with guidance about optimal methods to establish and interpret these. Clinical signs and symptoms are weighted as core or supportive, and biomarkers as indicative or supportive, based upon their diagnostic specificity and the volume of good-quality evidence available. Although carrying less diagnostic weight, supportive items are often valuable in clinical decision-making, acting as signposts to or adding evidence for a DLB diagnosis. The previous category of suggestive features is no longer used and those items, namely REM sleep behavior disorder (RBD), severe neuroleptic sensitivity, and low dopamine transporter (DAT) imaging, have been reassigned in the new scheme.

The revised criteria (table 1) generate categories of probable and possible DLB, corresponding to terminology previously used, describing the clinical presentations most typical of dementia associated with underlying Lewy-related pathology. Because of considerable pathologic heterogeneity, some dementia presentations associated with Lewy-related pathology are atypical, e.g., if abundant neocortical neuritic plaques and tangles are present in addition to Lewy bodies (LB), the clinical profile may more closely resemble AD rather than DLB.4,5 Such mixed pathology cases are common, explaining why up to half of carefully research-diagnosed patients with AD may have unsuspected Lewy-related pathology at autopsy.6 Criteria for the detection of such patients, previously characterized as the LB variant of AD,7 remain to be formulated.

Clinical features. Dementia, defined as a progressive cognitive decline of sufficient magnitude to interfere with normal social or occupational functions, or with usual daily activities, is an essential requirement for DLB diagnosis.

Although dementia screens such as the Mini-Mental State Examination (MMSE) and Montreal Cognitive Assessment are useful to characterize global impairment in DLB, neuropsychological assessment should include tests covering the full range of cognitive domains potentially affected. Disproportionate attentional, executive function, and visual processing deficits relative to memory and naming are typical.8,9,10 Measures of attention/executive function that differentiate DLB from AD and normal aging and that predict progression from mild cognitive impairment (MCI) to DLB include tests of processing speed and divided/alternating attention, e.g., Stroop tasks, trail-making tasks, phonemic fluency, and computerized tasks of reaction time. The spatial and perceptual difficulties of DLB often occur early; examples of useful probes include tasks of figure copy, e.g., intersecting pentagons, complex figure copy; visual assembly, e.g., block design, puzzle tasks; spatial matching, e.g., line orientation, size matching tasks; and perceptual discrimination, e.g., incomplete figures, incomplete letters, pareidolia tasks.10,11 Memory and object naming tend to be less affected in DLB, and are best evaluated through story recall, verbal list learning, and confrontation naming tasks, although some patients’ difficulties may be secondary to speed or retrieval task demands.

No DLB-specific assessment batteries have been developed, although recommendations have been made about suitable existing instruments11 and a composite risk score tool has been published.12

Core clinical features. Fluctuation. DLB fluctuations have been described in detail previously1,2 and are typically delirium-like,4,5 occurring as spontaneous alterations in cognition, attention, and arousal. They include waxing and waning episodes of behavioral inconsistency, incoherent speech, variable attention, or altered consciousness that involves staring or zoning out. Direct questioning of an informant about fluctuations may not reliably discriminate DLB from AD, but questions about daytime drowsiness, lethargy, staring into space, or episodes of disorganized speech do. These have been incorporated into scales that either score the severity and frequency of fluctuations derived from a clinical interview or use informant reports from semi-structured questionnaires.13–16 Recording variations in attentional performance using repeated computer-based tests offers an independent method.17 At least one measure of fluctuation should be documented when applying DLB diagnostic criteria. Fluctuations may also occur in advanced stages of other dementias, so they best predict DLB when they are present early.2

Visual hallucinations. Recurrent, complex visual hallucinations occur in up to 80% of patients with DLB and are a frequent clinical signpost to diagnosis. They are typically well-formed, featuring people, children, or animals, sometimes accompanied by related phenomena including passage hallucinations, sense of presence, and visual illusions.4,8 Patients are typically able to report these experiences, as are observant caregivers. Patient responses to their hallucinations vary both in degree of insight and emotional reaction to them. Assessment scales for characterizing and quantifying visual hallucinations are available.17

Parkinsonism. Spontaneous parkinsonian features, not due to antidopaminergic medications or stroke, are common in DLB, eventually occurring in over 85%.6,9 Parkinsonism in Parkinson disease (PD) is defined as bradykinesia in combination with rest tremor, rigidity, or both.18 Many DLB patients’ parkinsonism falls short of this, so documentation of only one of these cardinal features is required. Care should be taken particularly in older patients not to misinterpret physical signs due to comorbidity, e.g.,
### Table 1 Revised criteria for the clinical diagnosis of probable and possible dementia with Lewy bodies (DLB)

| Essential for a diagnosis of DLB is dementia, defined as a progressive cognitive decline of sufficient magnitude to interfere with normal social or occupational functions, or with usual daily activities. Prominent or persistent memory impairment may not necessarily occur in the early stages but is usually evident with progression. Deficits on tests of attention, executive function, and visuospatial ability may be especially prominent and occur early. |
| Core clinical features (The first 3 typically occur early and may persist throughout the course.) |
| Fluctuating cognition with pronounced variations in attention and alertness. Recurrent visual hallucinations that are typically well formed and detailed. REM sleep behavior disorder, which may precede cognitive decline. One or more spontaneous cardinal features of parkinsonism: these are bradykinesia (defined as slowness of movement and decrement in amplitude or speed), rest tremor, or rigidity. |
| Supportive clinical features |
| Severe sensitivity to antipsychotic agents; postural instability; repeated falls; syncope or other transient episodes of unresponsiveness; severe autonomic dysfunction, e.g., constipation, orthostatic hypotension, urinary incontinence; hypersomnia; hyposomnia; hallucinations in other modalities; systematized delusions; apathy, anxiety, and depression. |
| Indicative biomarkers |
| Reduced dopamine transporter uptake in basal ganglia demonstrated by SPECT or PET. Abnormal (low uptake) 123Iodine-MIBG myocardial scintigraphy. Polysomnographic confirmation of REM sleep without atonia. |
| Supportive biomarkers |
| Relative preservation of medial temporal lobe structures on CT/MRI scan. Generalized low uptake on SPECT/PET perfusion/metabolism scan with reduced occipital activity ± the cingulate island sign on FDG-PET imaging. Prominent posterior slow-wave activity on EEG with periodic fluctuations in the pre-alpha/theta range. |

**Probable DLB** can be diagnosed if:
- a. Two or more core clinical features of DLB are present, with or without the presence of indicative biomarkers, or
- b. Only one core clinical feature is present, but with one or more indicative biomarkers.

**Possible DLB** should not be diagnosed on the basis of biomarkers alone.

**Probable DLB** can be diagnosed if:
- a. Only one core clinical feature of DLB is present, with no indicative biomarker evidence, or
- b. One or more indicative biomarkers is present but there are no core clinical features.

**DLB** is less likely if:
- a. In the presence of any other physical illness or brain disorder including cerebrovascular disease, sufficient to account in part or in total for the clinical picture, although these do not exclude a DLB diagnosis and may serve to indicate mixed or multiple pathologies contributing to the clinical presentation, or
- b. If parkinsonian features are the only core clinical feature and appear for the first time at a stage of severe dementia. |

**Probable DLB** should be diagnosed when dementia occurs before or concurrently with parkinsonism. The term Parkinson disease dementia (PDD) should be used to describe dementia that occurs in the context of well-established Parkinson disease. In a practice setting the term that is most appropriate to the clinical situation should be used and generic terms such as Lewy body disease are often helpful. In research studies in which distinction needs to be made between DLB and PDD, the existing 1-year rule between the onset of dementia and parkinsonism continues to be recommended.

**Biomarkers.** Although direct biomarker evidence of LB-related pathology is not yet available for clinical diagnosis, several useful indirect methods are.

**Indicative biomarkers.** If one or more of these is found, associated with one or more core clinical features, probable DLB should be diagnosed. Dementia without any core clinical features, but with one or more indicative biomarkers, may be classified as possible DLB. Probable DLB should not be diagnosed on the basis of biomarkers alone.

**Reduced DAT uptake in basal ganglia demonstrated by SPECT or PET imaging.** The utility of DAT imaging in distinguishing DLB from AD is well-established, with sensitivity (78%) and specificity (90%). Figure 1 shows 123Iodine FP-CIT SPECT images in patients with AD, patients with DLB, and normal controls. When parkinsonism is the only core clinical feature of DLB in a patient with dementia, reduced DAT uptake warrants a probable DLB diagnosis provided that other disorders associated with cognitive impairment and reduced DAT uptake can be excluded, e.g., progressive supranuclear palsy, multisystem atrophy, corticobasal degeneration, and frontotemporal dementia. Normal DAT uptake may be reported in autopsy-confirmed DLB.
either because of minimal brainstem involvement and limited nigral neuron loss or a balanced loss of dopamine across the whole striatum, rather than predominantly in the putamen.

high accuracy. Larger studies, earlier in disease, suggest sensitivity (70%) and specificity (74%) slightly lower than needed for an indicative biomarker, although better than that reported for HMPAO-SPECT (65% and 64%).

Relative preservation of posterior or midcingulate metabolism on FDG-PET (the cingulate island sign) has been described in DLB, associated with less concurrent neurofibrillary pathology, but with no difference in Aβ load relative to AD (figure 4).

Prominent posterior slow-wave EEG activity with periodic fluctuations in the pre-alpha/theta range. Evidence is building to support quantitative EEG as a DLB biomarker, characterized by specific abnormalities in posterior derivations. These include a pre-alpha-dominant frequency, either stable or intermixed with alpha/theta/delta activities in pseudoperiodic patterns, which together have a predictive value >90% for the diagnosis of DLB compared with AD. These specific EEG patterns also correlate positively with the severity of clinically observed cognitive fluctuations and may be seen at the MCI stage.

Other imaging biomarkers. PET imaging shows increased Aβ brain deposition in >50% of patients with DLB, limiting its value to distinguish between AD and DLB. Combining biomarkers in a multimodal approach can improve diagnostic accuracy in distinguishing DLB and AD and provides information about mixed pathology and multisystem involvement. Tau PET imaging may have an important role, along with MTL atrophy, as a key indicator of coexisting AD pathology in DLB, predictive of clinical phenotype and progression.

Genetic and fluid biomarkers. The development of broadly applicable CSF, blood, peripheral tissue, or genotypic biomarkers for DLB remains elusive. Although it is clear that there is a substantial genetic contribution to DLB and that different genetic markers even within the α-synuclein gene (SNCA) may be associated with different LB syndromes, our understanding of the core genes involved remains limited. CSF α-synuclein is not yet proven as a biomarker, while Aβ, tau, and phospho-tau measurements may be more useful in determining concomitant AD pathology or predicting cognitive decline. Glucocerebrosidase (GBA) mutations are overrepresented in DLB but most individuals with DLB do not have them. It is premature to recommend genetic testing in a clinical setting, either for confirmation of diagnosis or for prediction of disease, and genetic studies should currently be limited to research settings.
Clinical management. The management of patients with DLB is complex, requiring a multifaceted approach. Key elements include a thorough initial evaluation to ensure accurate diagnosis; early identification of signs and symptoms requiring intervention; engagement, education, and support of care providers; and a multidisciplinary team approach. Patients with DLB are prone to mental status worsening, including delirium, in the face of comorbid medical disorders. Dopaminergic therapies and anticholinergic medications can adversely affect cognition and behavior, leading to confusion and psychosis. Treatment of DLB is focused on the cognitive, psychiatric, motor, and other nonmotor symptoms that represent the core or most common features of the disorder. A combination of pharmacologic and nonpharmacologic approaches is optimal. As the evidence base to support particular treatments remains limited, the recommendations outlined below remain based, in part, upon consensus expert opinion.

Nonpharmacologic interventions. Given both the limited evidence for efficacy and the potential increased morbidity and mortality risks associated with pharmacologic treatments in DLB, there is a need to develop and test nonpharmacologic management strategies. Interventions can be patient- or caregiver-focused, or both. More research in this area has been conducted in AD and PD than in DLB, with promising preliminary evidence for exercise (both motor and cognitive benefits), cognitive training, and caregiver-oriented education and training to manage psychiatric symptoms including agitation and psychosis.

Pharmacologic management. Cognitive symptoms. Meta-analyses of Class I clinical trials of rivastigmine and donepezil support the use of cholinesterase inhibitors (CHEIs) in DLB for improving cognition, global function, and activities of living, with evidence that even if patients do not improve with CHEIs they are less likely to deteriorate while taking them. A combination of pharmacologic and nonpharmacologic approaches is optimal. As the evidence base to support particular treatments remains limited, the recommendations outlined below remain based, in part, upon consensus expert opinion.

Neuropsychiatric symptoms. CHEIs may produce substantial reduction in apathy and improve visual
hallucinations and delusions in DLB.49 Since anxiety and agitation are sometimes driven by psychosis, there may be secondary benefits in these. The use of antipsychotics for the acute management of substantial behavioral disturbance, delusions, or visual hallucinations comes with attendant mortality risks in patients with dementia, and particularly in the case of DLB they should be avoided whenever possible, given the increased risk of a serious sensitivity reaction.50 Low-dose quetiapine may be relatively safer than other antipsychotics and is widely used, but a small placebo-controlled clinical trial in DLB was negative.51 There is a positive evidence base for clozapine in PD psychosis, but efficacy and tolerability in DLB have not been established. Newer drugs targeting the serotonergic system, such as pi-mavanserin,52 may be alternatives, but controlled clinical trial data in DLB are needed. Although depressive symptoms are common in DLB, trial data are scant. In alignment with general advice on depression in dementia, selective serotonin reuptake inhibitors, serotonin-norepinephrine reuptake inhibitors, and mirtazapine are options in DLB with treatment guided by individual patient tolerability and response.

Motor symptoms. Parkinsonism is often less responsive to dopaminergic treatments in DLB than in PD and their use may be associated with an increased risk of psychosis, although some patients may benefit from levodopa preparations introduced at low doses and increased slowly to the minimum required to minimize motor disability without exacerbating psychiatric symptoms.53,e28 Patients at risk of falling may benefit from safety assessments, as well as bone mineral density screening, and assessment of vitamin D status, to manage risk of traumatic fractures.

Other symptoms. A wide range of other symptoms can occur in DLB, including autonomic and sleep/wakefulness disturbances, which have profound negative sequelae for quality of life in both patients and their families. In the absence of DLB-specific trial data for these symptoms, clinicians base their treatment decisions on clinical experience, expert opinion, or evidence-based recommendations developed in other diseases, e.g., cautious bedtime use of clonazepam may reduce the risk of sleep-related injuries in
patients with DLB with RBD but carries a risk of worsening cognition and gait impairment, melatonin being a possibly safer option.

**Pathology.** The previously published methods for pathologic assessment and diagnosis of DLB should continue to be used with only a few modifications, shown in Table 2, which predicts the likelihood that the pathologic findings will be associated with a typical DLB clinical syndrome, i.e., cases with high likelihood are expected to fulfill clinical criteria for probable DLB, whereas low likelihood cases may have few or no DLB clinical features.

Table 2 assigns categories of AD neuropathologic change according to National Institute on Aging–Alzheimer’s Association criteria (no, low, intermediate, and high), and adds previously omitted categories of Lewy-related pathology including olfactory bulb only and amygdala predominant. Both of these are considered to be low-likelihood DLB but may in the future be useful in assessing prodromal disease. Further efforts are required to develop better interrater reliability for Lewy-related disease subtypes (olfactory bulb only, amygdala predominant, brainstem, limbic [transitional], and diffuse neocortical). Table 2 also includes an assessment of substantia nigra neuronal loss (none, mild, moderate, and severe) in order to subclassify cases into those likely or not to have parkinsonism (DLB-P and DLB-no P).

**FUTURE DIRECTIONS.** Since publication of the 2005 consensus report, DLB has been confirmed as a major dementia subtype, categorized in DSM-5 as neurocognitive disorder with LB, and distinguished from neurocognitive disorder due to PD. The consensus group remains supportive of the 1-year rule distinguishing DLB from PD dementia, because as originally stated, this arbitrary cutoff remains useful, particularly in clinical practice. Based as it is on expert opinion, the time period may need modification when the genetic underpinnings, pathophysiologic mechanisms, and prodromal states of these disorders are sufficiently understood to enable a data-driven solution.

There is an urgent need to develop guidelines and outcome measures for clinical trials in DLB, both symptomatic and disease-modifying, nonpharmacologic and pharmacologic. DLB researchers can build upon experience gained in AD and PD; additional issues for them to consider include subtyping of patients on the basis of clinical or biomarker criteria and selecting target symptoms and outcome measures appropriate to DLB. It will be necessary to manage potential confounding factors that are common in DLB, e.g., fluctuations in alertness and fatigue, active hallucinations, and concomitant use of cognitive enhancing and psychiatric medications. Such considerations will need to be applied when designing clinical trials across the spectrum of clinical syndrome of DLB from prodromal and presymptomatic stages, still to be identified, to overt dementia.

Suggested strategies to progress critical areas of biological research include collecting samples from large population-based cohorts and developing a publicly available DLB genetic database and a repository for DLB exome data. Family studies are needed to find and confirm genes, requiring clinicians to take detailed family histories seeking evidence not only of DLB, PD, and AD and other dementias, but also of RBD and supportive features.

In order to make progress in deciphering biological mechanisms at play in DLB including GBA and inflammatory pathways, it will be necessary to develop robust animal models that capture the true neuropathologic and behavioral abnormalities of DLB, and to identify possible disease-specific

molecular differences in α-synuclein, tau, and Aβ among DLB, PD, PD dementia, and AD. The latter includes characterization of possible molecular strains of misfolded or pathologic α-synuclein, postranslational modifications in degradation and clearance processes, and transmission and propagation. It will be increasingly important to study protein interactions among α-synuclein, Aβ, and tau. Finally, there is an unmet need to characterize biological effects of identified genetic risk factors, including APOE, GBA, and SNCA, as well as to model and analyze gene–environmental interactions.

In order to best advance DLB research, global harmonization efforts are required to create networks of researchers and research participants who share common platforms for data and biomarker collection, outcome measures for clinical–translational research, and shared terminology across language, cultures, and traditions. Consideration might be given to creating an international patient and caregiver association to serve as advocates for private and public funding; identifying obstacles to the pharmaceutical industry sponsoring DLB research; bridging relationships with the PD and AD world research communities; creating a plan for reimbursement for DLB clinical care, drugs/devices, and biomarkers; and increasing interdisciplinary and interprofessional communication regarding the challenges facing clinicians, patients, and caregivers. Finally, priority needs to be given to helping patients and carers to inform themselves about the disease, its prognosis, best available treatments, ongoing research, and how to get adequate support.

Bohnén receives research support from the NIH, Department of Veterans Affairs, and the Michael J. Fox Foundation. L. Bonanni reports no disclosures relevant to the manuscript. J. Bras was supported by a fellowship from the Alzheimer’s Society and funding from the Lewy Body Society and Parkinson’s UK. P. Brun叮 has received commercial support as a consultant to Renovo Neural, Inc., Roche, Teva/Lundbeck, and AbbVie. He has received commercial support for grants/research from Renovo and Teva/Lundbeck. D. Burn and A. Chen-Plotkin report no disclosures relevant to the manuscript. J. Duda serves on the Editorial Board for npj Parkinson’s Disease and has received research support from the US Department of Veterans Affairs, NIH, and the Michael J. Fox Foundation for Parkinson’s Research. O. El-Agnaf reports no disclosures relevant to the manuscript. H. Feldman receives research funding from the NIH, the Canadian Institutes of Health Research, the Weston Foundation, UC Cures for Alzheimer’s Disease, and Heart and Stroke Foundation of Canada. He has served as a consultant on clinical trials sponsored by TauRx, Hoffman LaRoche, and Lilly. He currently serves on the scientific advisory boards for the Tau Consortium, Tau RX, and the Alzheimer Society of Canada Research Policy. He has performed service agreements for UCSF/UBC with Genentech Banner Health, Eisai, Arena, and Merck. He receives royalties for the publication of An Atlas of Alzheimer’s Disease (Informa Health, 2007). He has a US patent: PCT/US 2007/070008. T. Ferman, D. fynche, and H. Fujishiro report no disclosures relevant to the manuscript. D. Galasko is funded by NIH grant AG05131, the Michael J. Fox Foundation, and the California Institute for Regenerative Medicine. He has received funding from TV Pharmaceuticals and Eli Lilly, Inc., for consultation, from Eli Lilly and Prothera for service on Data Safety Boards, and payment from Biomed Central as Editor for Alzheimer’s Research and Therapy. J. Goldman has received grant/research support from the NIH, Michael J. Fox Foundation, Rush University, Parkinson Disease Foundation, Acadia, and Biotie (site PI), consulting fees from Acadia, Biogen, Pfizer, and Teva; and honorary from the International Parkinson and Movement Disorder Society, American Academy of Neurology, MedEdicus, and Pri-Med. S. Gomports reports no disclosures relevant to the manuscript. N. Graff-Radford is in a member of the Board of Directors of Alzheimer’s North Carolina. He receives research support from NIH, TauRx Therapeutics, Navidea Biopharmaceuticals, Axovant Sciences, Neurim Pharmaceuticals, and AbbVie. W. Kukull is funded primarily by NIH grant U01 AG010676 “National Alzheimer’s Coordinating Center” and has no other relevant disclosures. He is a Senior Associate Editor for Alzheimer’s and Dementia and is also on the editorial board of Alzheimer’s Disease and Associated Disorders (nonrenumerated positions). V. Lee may accrue revenue in the future on patents submitted by the University of Pennsylvania wherein she is coinventor and she received revenue from the sale of Avid to Eli Lilly as coinventor on imaging-related patents submitted by the University of Pennsylvania. She receives research support from the NIH, GSK, Jansen, Biogen, and several nonprofits. J. Leverenz has served as a consultant for Axovant, GE Healthcare, Navidea Biopharmaceuticals, and Takeda and is funded by grants from the Alzheimer’s Drug Discovery Fund, Genzyme/Sanofi, and Jane and Lee Seidman Fund, Lewy Body Dementia Association, Michael J. Fox Foundation, and NIH (RF1AG091495, P50NS062684, U01NS010616). S. Lewis, C. Lippa, and A. Lunde report no disclosures relevant to the manuscript. M. Madsen has no disclosures relevant to this work. Outside of this work, Dr. Le- Maselli has served as an Associate Editor for Current Pharmaceutogenomics and Personalized Medicine; served as an advisor to Bioscape Medical Imaging CRO, UCB, and GE Healthcare; received honorary and travel/accommodations/meeting expenses from Novartis and Teva; received royalties from Henry Stewart Talks Ltd.; received peer-reviewed research grants from Canadian Institutes of Health Research, Early Researcher Award—Ministry of Economic Development and Innovation of Ontario, Ontario Brain Institute, Sunnybrook AFP Innovation Fund, Alzheimer’s Drug Discovery Foundation (ADDF), Brain Canada, Heart and Stroke Foundation Centre for Stroke Recovery, Weston Brain Institute, and Washington University; received investigator-initiated research support from Teva; received contract research support from Axovant; and received salary support from the Department of Medicine at Sunnybrook Health Sciences Centre and University of Toronto and from the Sunnybrook Foundation. In addition, Dr. Madsell has a patent US 14/674,606 pending, a patent PCT/US15/023618 pending, a patent AR 2015010101 pending, a patent US 9,376,606 pending, and a patent US 9,357,160 pending. D. McLean reports no disclosures relevant to the manuscript. B. Mollenhauer has received independent research grants from TEVA-Pharma, Desitin, Boehringer Ingelheim, and GE Healthcare, and honorary for consultation from Bayer Schering Pharma AG, Roche, AbbVie, TEVA-Pharma, and Biogen, and for presentations from GlaxoSmithKline, Orion Pharma, and TEVA-Pharma, and travel costs from TEVA-Pharma. B.M. is a member of the executive steering committee of the Parkinson Progression Marker Initiative of the Michael J. Fox Foundation for Parkinson’s Research and has received grants from the BMBF, EU, Deutsche Parkinson Vereini- gung, Michael J. Fox Foundation for Parkinson’s Research, and Stif- fer-Verband für die deutsche Wissenschaft, and has scientific collaborations with Roche, Bristol-Myers Squibb, Lilly Lilly, Covance, and Biogen. T. Montine reports no disclosures relevant to the manuscript. E. Moreno is a full employee of GE Healthcare and has been involved in the clinical development of DaTSCAN for the diagnosis of D LB. E. Mori received honorary from serving on the scientific advisory board of Eisai, grants and personal fees from Eisai, Daiichi Sankyo, Novartis, and FUJIFILM RI, and personal fees from Johnson & Johnson, Otsu, and Nihon Medi-Physics. M. Murray is funded by the Ed and Ethel Moore Alzheimer’s Research, and Stifter-Verband für die deutsche Wissenschaft, and has scientific collaborations with Roche, Bristol-Myers Squibb, Eli Lilly, Covance, and Biogen. T. Montine reports no disclosures relevant to the manuscript. E. Moreno is a full employee of GE Healthcare and has been involved in the clinical development of DaTSCAN for the diagnosis of DLB. E. Mori received honorary from serving on the scientific advisory board of Eisai, grants and personal fees from Eisai, Daiichi Sankyo, Novartis, and FUJIFILM RI, and personal fees from Johnson & Johnson, Otsu, and Nihon Medi-Physics. M. Murray is funded by the Ed and Ethel Moore Alzheimer’s Disease Research Program (6AZ01) and Gerstner Family Career Development Award. J. O’Brien has acted as a consultant for GE Healthcare, Cytos, TauRx, Axona, Piramal, and Lilly and has received grants from Avid (Lilly). S. Orimo received honorary for sponsored lectures from FUJIFILM RI Pharma Co Ltd. R. Postuma received grants from the Fonds de la Recherche en Sante Quebec, the Canadian Institute of Health Research, the Parkinson Society, the Weston-Garfild Founda- tion, and the Webster Foundation, as well as funding for consultancy.
from Biote and Roche, and speaker fees from Novartis Canada and Teva Neurosciences. S. Ramaswamy is an employee of Axovant Sciences, Inc. He has been involved in the design and execution of the clinical trials in Lewy body dementia conducted by Axovant. O. Ross reports no disclosures relevant to the manuscript. D. Salmon is a consultant for Takeda Pharmaceuticals and is supported by NIA grant AG05131. A. Singleton is an employee of the Intramural Program of the NIH. A. Taylor is an employee of the Lewy Body Dementia Association. A. Thomas has received support from GE Healthcare, the manufacturer of 123I-FP-CIT (DaTSCAN), for investigator-led research. P. Tiraboschi reports no disclosures relevant to the manuscript. J. Toledo has received research support from Eli-Lilly. J. Trojanowksi may accrue revenue in the future on parents submitted by the University of Pennsylvania wherein he is co-inventor and he received revenue from the sale of Avid to Eli Lilly as co-inventor on imaging-related patents submitted by the University of Pennsylvania. He receives research support from the NIH, GSK, Janssen, Biogen, and several nonprofits. D. Tsuang serves on the Editorial Board of the American Journal of Medical Genetics, Neuropsychiatric Section, and receives research funding from the NIH and Veterans Affairs Research and Development. Z. Walker has received funding for travel, consultancy, speaker fees, and research support from GE Healthcare (GEHC). M. Yamada received honoraria for sponsored lectures and research grant from Fujifilm RI Pharma Co. Ltd. K. Kosaka reports no disclosures relevant to the manuscript. Go to Neurology.org for full disclosures.

Received September 30, 2016. Accepted in final form March 30, 2017.
