Neurology® Published Ahead of Print articles have been peer reviewed and accepted for publication. This manuscript will be published in its final form after copyediting, page composition, and review of proofs. Errors that could affect the content may be corrected during these processes. Videos, if applicable, will be available when the article is published in its final form.
Case Summary
A 52-year-old man complained of right eye closure whenever eating. He had suffered a right sided Bell’s palsy around 12 months prior. Examination showed unilateral eye closure on jaw opening or lateral jaw movements, related to active contraction of the entire orbicularis oculi muscle, in addition to ipsilateral hemifacial spasm (Video 1). Marin-Amat syndrome is an acquired synkinesis occurring most frequently after Bell’s palsy and is the opposite of the more common Marcus Gunn phenomenon, in which there is eyelid retraction on jaw opening or horizontal movement. It is sometimes erroneously termed an “inverse” Marcus Gunn, although this is a congenital condition in which there is inhibition, and resulting ptosis, of the levator palpebrae muscle on mouth opening, rather than the active contraction of orbicularis oculi seen in Marin-Amat syndrome. Botulinum toxin to the orbicularis oculi muscle, otherwise generally ineffective in the Marcus Gunn phenomenon, can therefore be therapeutic.
