A 46-year-old man suffered a complete C6 spinal cord injury with minimal recovery. Two years later, he underwent olfactory stem cell injection into the cervical post-traumatic syrinx but developed progressive weakness. A C5 syringo-subarachnoid shunt was placed, but his strength declined further, so he underwent syrinx evacuation. Upon dural opening, white gelatinous material exuded under pressure (Figure 1). Pockets of similar material were evacuated. Pathology identified respiratory epithelium and seromucinous glands within fibrous stroma (Figure 2). Within four months, he regained deltoid and bicep function.

Olfactory stem cells have been proposed as an experimental treatment for functional improvement following traumatic spinal cord injury; intrathecal administration improved function in one patient.\(^1\) Although mesenchymal stromal cell injection in syrinx has shown promise in reducing syrinx size and improving function, careful monitoring is needed for potential side effects.\(^2\)
